

# List of Known and Possible Bugs(2024/04/03)

1. Production server completely crashes for predicting a large amount of fitbit file data. This is likely due to a lack of memory in our production servers that causes a complete crash of the system.
2. Data processing failure for fitbit/apple watch data because of invalid data format
  - Context: Missing files or wrong format can lead to failure to process a batch of watch files.
  - Expected: The error thrown should let the user of steps to correct failure.
  - Actual: The actual console error is thrown directly resulting in an extremely long error and non helpful/user friendly message
3. Vulnerability to DDos attacks (but there is not too much that could be done on our side to fully prevent it)
4. User can include unsafe passwords (not a bug perse but may cause insecurity issues)
5. If there are too many files to process (e.g: 10 or more) the text of the process button will be cropped.
6. Rollbar is getting spammed way too much on visits to pages
